ABSTRACT

Latour (1985) conducted a stratified strip transect aerial survey of Banks Island in 1982. We re-analyzed the data using current standard statistical methods and measured linear distances and areas using current GIS technology. The population estimates derived for Peary caribou and muskoxen during our analyses did not differ significantly from the original analyses. The area of Banks Island surveyed in 1982 was originally over estimated, as a result when we extrapolate the results of our analyses to the island, the mean estimates for the number of Peary caribou and muskoxen numbers are approximately 950 and 1,600 higher, respectively than the results of the original extrapolation. Maps showing the distribution of non-calf and calf Peary caribou and muskoxen on the island are provided.

INTRODUCTION

Latour (1985) conducted one of the first systematic surveys of Peary caribou and muskoxen on Banks Island in 1982. Latour's (1985) original survey data and maps were archived at the Department of Environment and Natural Resources regional office in Inuvik, NT. The methods that were available to biologists working in remote locations to measure areas of survey blocks and lengths of transect lines were relatively crude in 1982. The technology that is available for geo-spatial analyses has advanced significantly since 1982. The use of computerized geographic information systems (GIS) and global positioning systems (GPS) and associated software has become commonplace among field biologists. As a result, survey areas and transect lengths can be measured more precisely. The latitude and longitude locations of wildlife sightings are commonly documented in the field using a GPS. We used current GIS, GPS, and population estimation programs to re-analyze the results of the 1982 Banks Island survey. The results of surveys completed in 1985 (McLean et al., 1986), 1987 (McLean, 1992), 1989 (McLean and Fraser, 1992), 1992 (Nagy et al., 2007b), 1994 (Nagy et al., 2007c), 1998 (Nagy et al., 2007d) will be reanalyzed in a similar manner in the future to standardize all population estimates derived for Peary caribou and muskoxen on Banks Island. The results of our reanalysis of the 1982 Banks Island survey data are presented here.

METHODS

We re-analyzed the results of the 1982 Peary caribou and muskox survey conducted by Latour (1985) using ArcView 3.2 GIS software (Environmental Systems Research Institute) and GPS (OziExplorer GPS Mapping Software). We digitized the location of each observation made using OziExplorer. Each labeled each waypoint with Latour's (1985) original field sighting numbers. The resulting OziExplorer waypoint files were parsed using Microsoft Excel and the data for each observation was then entered from Latour's (1985) field data sheets. At the end of this process the survey data were geo-referenced. This allowed us to map the distribution of Peary caribou and muskoxen observed during the survey.

In addition, we used the original field survey maps (Latour, 1985):

- to create shape files for each survey block so that total area of each could be measured using ArcView 3.2 GIS software, and
- to digitize the locations of the end points of each transect flown so that the length of each transect could be determined using OziExplorer.

The specifications of the projection used are as follows: Lambert Conformal Conic, NAD83, Central Meridian: 123.0 W, Latitude of Origin: 73.0 N, SP1: 72.0 N, SP2: 74.0 N.

Latour (1985) surveyed 7 blocks but analyzed the data as 3 blocks by pooling the data for blocks in the southern portion of the island. We analyzed the data as presented in Appendix A (Latour, 1985) using Aerial2 Version 3 (Krebs, 1999) but used strata areas and transect lengths measured using ArcView 3.2

GIS software and OziExplorer. We also analyzed the data for each of 7 survey blocks separately using Aerial2 Version 3. Estimates of non-calf, calf, and all caribou and muskoxen, respectively, were derived for each survey block. Population and variance estimates from each stratum were combined to derive an overall population and population variance estimate for non-calf, calf, and all caribou and muskoxen, respectively, in all survey blocks.

The estimation of population number and variance from stratified surveys is given in Compton *et al.* (1995) cited by Johnson *et al.* (2004). The total population number is the summation of individual strata estimates (equation 1):

$$\hat{N}_{total} = \sum_{h=1}^{L} \hat{N}_{h}$$

where there are *L* strata units. Assuming that the selection of sample units within each strata is independent of other strata units, the variance is estimated as the sum of individual variance estimates for each strata, or (equation 2):

$$\operatorname{var}_{total} = \sum_{h=1}^{L} \operatorname{var}_{h}$$

Confidence intervals for the population estimate can be approximated by (equation 3):

$$\hat{N}_{total} \pm t \sqrt{\text{var}_{total}}$$

The degrees of freedom (d) for the t-statistic can be approximated by the following formula (equation 4):

$$d = \frac{\left(\sum_{h=1}^{L} a_h s_h^2\right)^2}{\left[\sum_{h=1}^{L} \left((a_h s_h^2)^2 / (n_h - 1)\right)\right]}$$

where $a_h = N_h(N_h - n_h)/n_h$ where N_h is the possible number of transects in an individual block and n_h is the actual number of transects flown. The sample variance from each block is denoted as s^2 in the above formula, and L is the total number of strata (Compton *et al.*, 1995) cited by Johnson *et al.* (2004). This assumes that the population estimates and variance estimates from each strata are unbiased and independent.

We derived the percent of the island survey as follows:

= population estimate for the area surveyed / (area survey / area of the island) (as a decimal value)

We estimated the upper and lower 95% CI for the resulting whole island population estimate as follows:

= population estimate for area surveyed ± [population estimate for area surveyed × (95% CI / population estimate for area surveyed)].

We mapped the distribution of calf and non-calf caribou and muskoxen using ArcView 3.2 GIS software (Environmental Systems Research Institute)

RESULTS AND DISCUSSION

The survey blocks and transects flown are shown in Figure 1. The sites where non-calf and calf Peary caribou and muskoxen were observed during the 1982 survey are shown in Figures 2, 3, 4, and 5. Table 1 provides a summary of the population estimates for non-calf Peary caribou and muskox based on a reanalysis of the data for 3 strata as presented in Appendix A by Latour (1985). Table 2 provides population estimates for non-calf and calf Peary caribou based

on an analysis of data for 7 strata using Latour's (1985) original field data. Similarly, Table 3 provides population estimates for non-calf and calf muskoxen based on an analysis of data for 7 strata using data Latour's (1985) original field data. Table 4 provides a summary of comparison made between area and population estimates derived by Latour (1985) and our re-analysis of the data. Appendix A provides the transect data for the 1982 survey based on Latour (1985). Appendix B and C provide the data associated with sightings of Peary caribou and muskoxen, respectively, made during the 1982 survey based on Latour (1985) original field data.

Size of Survey Blocks and Banks Island

Latour (1985) indicated that 64,507 km² or 91.4% of the island (area 70,582 km²) was surveyed during 1982. Our analyses indicate that 56,333 km² or 79.8% of Banks Island was surveyed. The size of the area surveyed was 8,174 km² smaller than originally reported.

Peary caribou

The population estimate based on re-analysis of the data for 3 strata for Peary caribou as presented by Latour (1985) and pooling the variance estimates for the 3 strata was 7.391 ± 2.272 (95% CI). The whole island estimate was 8.087 ± 2.486 (95% CI). In comparison, the population estimate based on an analysis of the data for 7 strata based on Latour (1985) and pooling the variance

estimates for the 7 strata was 7,212 \pm 2,336. The whole island estimate was 9,036 \pm 2,927 (95% CI).

The population estimates for the 3 strata vs. 7 strata analyses were not significantly different (t²=0.117, DF=35, P>0.05). Similarly, the whole island population estimates based on extrapolating results of the 3 strata vs. 7 strata analyses were not significantly different as the 95% Cl's overlapped. However, the mean whole island estimate based on the 7 strata analysis was 949 non-calf caribou higher than that for the 3 strata analysis. This difference was largely due to the fact that 79.8% of the island was actually surveyed rather than 91.4% as originally reported. The magnitude of this difference may have significant implications for other analyses or management decisions.

Muskox

The population estimate based on re-analysis of the data for 3 strata for muskox as presented by Latour (1985) and pooling the variance estimates for the 3 strata was 9.925 ± 2.550 (95% CI). The whole island estimate was 10.860 ± 2.790 (95% CI). In comparison, the population estimate based on an analysis of the data for 7 strata based on Latour (1985) and pooling the variance estimates for the 7 strata was 9.961 ± 2.432 . The whole island estimate was 12.481 ± 3.047 (95% CI).

The population estimates for the 3 strata vs. 7 strata analyses were not significantly different (t²=0.022, DF=36, P>0.05). Similarly, the whole island population estimates based on extrapolating results of the 3 strata vs. 7 strata

analyses were not significantly different as the 95% CI's overlapped. However, the mean whole island estimate based on the 7 strata analysis was 1,621 non-calf muskoxen higher than that for the 3 strata analysis. Again, this difference was largely due to the fact that 79.8% of the island was actually surveyed rather than 91.4% as originally reported. The magnitude of this difference may have significant implications for other analyses or management decisions.

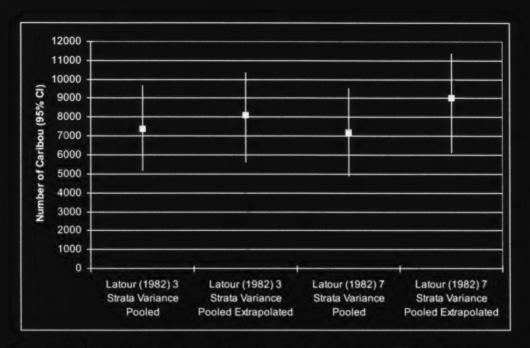

Figure 6. Population estimates (95 percent confidence intervals) for Peary caribou derived by re-analyzing (Latour 1985) survey data¹.

- Latour (1985) 3 strata variance pooled: Latour (1985) surveyed 7 blocks but analyzed the
 data as 3 blocks by pooling the data for blocks in the southern portion of the island. We
 combined the population and population variance estimates for these blocks as given in
 Table 1 to derive an overall population and population variance estimate and the
 associated SE and 95% confidence intervals for non-calf caribou.
- Latour (1985) 3 strata variance pooled extrapolated: based on Latour's (1985) area estimates, 64,507 km² or 91.4% of Banks Island was surveyed. We divided the mean population estimate and associated upper and lower 95% confidence intervals by 0.914 to derived a non-calf caribou population estimate for the island (70,582 km²).
- Latour (1985) 7 strata variance pooled: Latour (1985) surveyed 7 blocks but pooled the
 data for blocks in the central and southern portion of the island. We analyzed the data for
 each of the 7 survey blocks separately using Aerial2 Version 3 (Krebs 1999) and
 combined the population and population variance estimates for these blocks to derive an
 overall population and population variance estimate and associated SE and 95%
 confidence intervals for non-calf, calf, and all caribou.
- Latour (1985) 7 strata variance pooled extrapolated: based on our area estimates, 56,333 km² or 79.8% of Banks Island was surveyed. We divided the mean population estimate and associated upper and lower 95% confidence intervals by 0.798 to derived a non-calf caribou population estimate for the island (70,582 km²).

¹ The following analyses were completed:

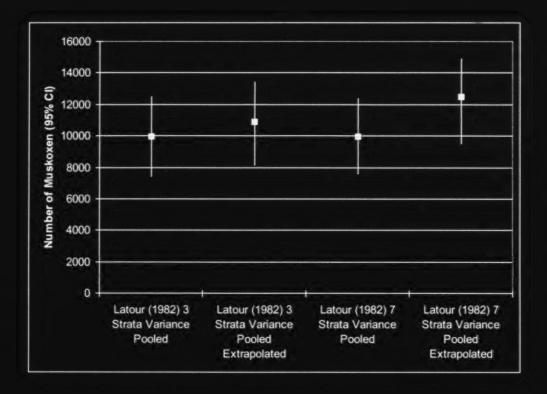

Figure 7. Population estimates (95 percent confidence intervals) for muskoxen derived by re-analyzing Latour's (1985) survey data¹.
